1. Field of the Invention This invention relates to personal vehicle diagnostics which are carried out in the vehicle or which are carried out in a shop or other location remote from the vehicle. 2. Description of the Prior Art Generally, the vehicle operator controls the various components of a vehicle system using switches such as buttons or through foot pedal controls. Typically, such switches are of the momentary contact type or the momentary contact and persistent nature which requires a "take" action to actuate the switch. For example, several switches such as door switches, trunk lid switch, tail lamp switch, windscreen wiper switch and the like, are actuated by the vehicle operator in a manner such that a power circuit is completed or interrupted for a brief duration. A disadvantage associated with using switches on these vehicle components is that these switches may be of such a position that when actuated the switch connects the power circuit for a brief duration. For example, the door switch may be positioned such that when actuated, it connects the power circuit to the door latch solenoid for a brief duration for actuating the latch solenoid in order to disengage the door from the vehicle body in order to open the door. If the vehicle door fails, the operator knows that this type of door latch switch acts as a power circuit interrupter for a short duration and that the door latches will not release and the operator may actuate other vehicle components to open the door. Similarly, other vehicle switches such as trunk lid switch, tail lamp switch, and the like, fail when the switch is positioned such that it provides power to the switch and thereby powers the vehicle component to be actuated. Attempts to overcome this problem have been made. For example, various vehicle

diagnostics systems such as that of U.S. Pat. No. 4,511,852, which is owned by the assignee of the present application, described an application where a vehicle diagnostics device is provided to interrupt a power circuit to various vehicle switches by sensing a current and by delaying the interruption of the power circuit to the switch until after the power circuit is opened for a predetermined time period. This approach overcomes the disadvantages associated with the switch being actuated when in its "closed" position by providing a secondary switch which is automatically triggered once the "take" action or closure of the power switch is sensed. However, the vehicle diagnostics system disclosed in U.S. Pat. No. 4,511,8

. Therefore, for each base station, the packet success rate can be written as:
$$\begin{matrix} {\eta\left({ t} \right) = \frac{d\left(t \right)}{d\left(t \right) + u\left(t \right)}} \\ \end{matrix}$$
where *d*(*t*) is the aggregate traffic from all the base stations and *u*(*t*) is the aggregate traffic from erroneous packets. Therefore, *eta*(*t*) is the probability of the transmission being successful. The unit of *u*(*t*) is bits/slot, assuming that one packet is transmitted in a slot. Let us assume that the packet is successfully transmitted when *T* bits/slot are successfully transmitted on average and the number of packets sent in a slot is Poisson distributed with mean *λT*. We derive the probability of packet success per slot for the packet success rate *eta*(*t*) as:
$$\begin{matrix} {E\left\lbrack {\eta\left(t \right)\, \mid \,\lambda T} \right\rbrack = \lambda T\frac{\frac{\lambda T}{\lambda T}}{\frac{\lambda T}{\lambda T} + 1} = \frac{\lambda T}{\lambda T + 1} =$$

$$\frac{\lambda}{\lambda + 1}.} \\ \end{matrix}$$ We rewrite this probability as a function of *λ* to show that it grows linearly with *λ* as claimed. Thus, given the fixed packet success rate, the packet success probability is proportional to the average number of packets in each slot. When *λ* is large enough, the packet success probability becomes equal to one, indicating that it is very likely that the packet will be successful.

===========================

The performance of the packet transmission in IEEE 802.11n WLAN is evaluated by using ns-2 software package \[[@B24]\]. A wireless LAN is modeled in ns-2 as a MBS (macro base station) and an MS (micro base station). The MBSs are placed at the center of a square indoor floor map with the lattice dimensions equal to 80 meters. Two MBSs are used in the simulation to
